Understanding the dynamics of central bank's credibility  
via heterogenous new Keynesian framework

PIER Research Workshop

ลับ

Wide agreement on a crucial issue for the next generation of policy models for central banks: need to allow for much more heterogeneity among the decision-making units (households, firms) in the economy — unlike the representative-agent structure of first-generation DSGE models (e.g., Smets and Wouters, 2007)

**Michael Woodford (2021, Conference on Heterogeneity in Macroeconomics)**

We develop a heterogeneous agent new Keynesian model in which representative agents have distinct risk-aversion coefficient ...

... and update their belief on the distribution of population across level of risk aversions.

$$\tilde{c}_{h,t} = \mathbb{E}[\tilde{c}_{h,t+1}] - \frac{1}{\sigma'}(\tilde{r}_t - \mathbb{E}[\pi_{t+1}]) + \epsilon_{h,t}$$

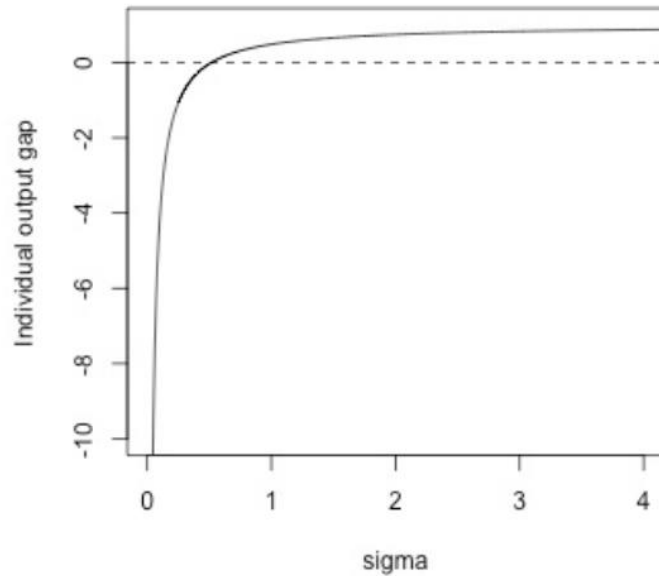

$$f_t(\sigma | Y = y_t, P = \pi_t) = \frac{f_t(Y = y_t, P = \pi_t | \sigma) f_t(\sigma)}{f_t(Y = y_t, P = \pi_t)}$$

The level of risk-aversion can roughly represent the perception of how credible the central bank is.

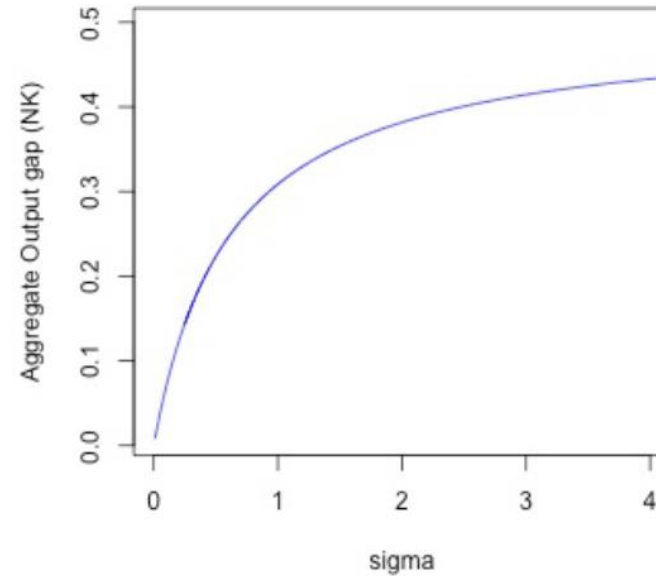

Understanding the dynamics of the distribution of risk-aversion coefficient can help policymaker investigate policy options and trade-offs.

# Heterogeneous belief and (contingent) decisions when there is 1-unit demand shock

Individual consumption  
decision differs greatly

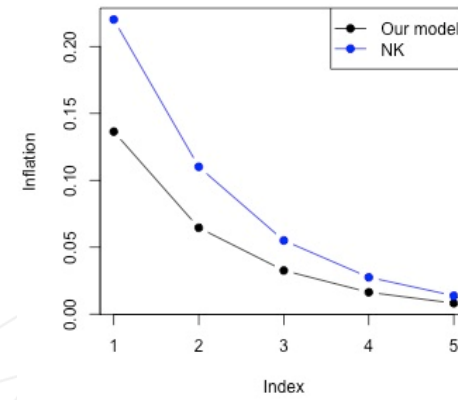

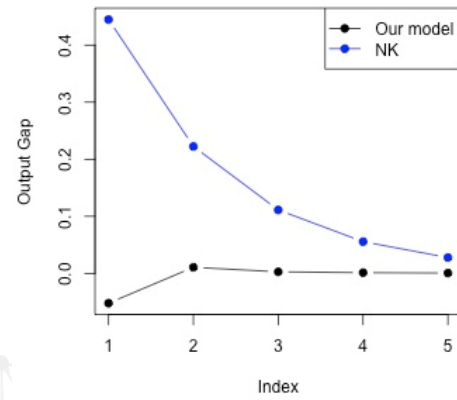

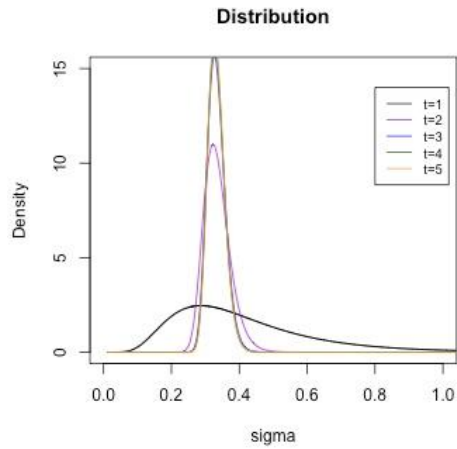

Compared to  
result from standard NK Model

# Monetary policy implications when there is 1-unit demand shock and the majority of households have low risk-aversion coefficients

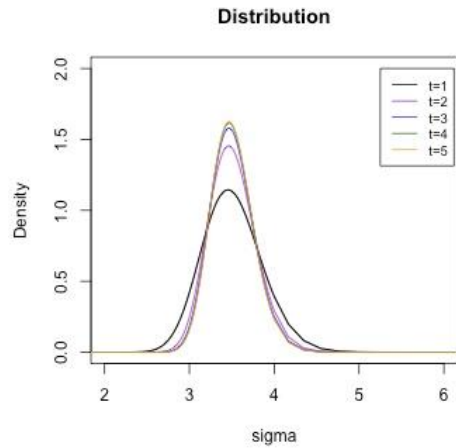

The household readjusts their risk-aversion coefficient and the value tends to converge

Output gap closes very quickly

Inflation converges quicker and has less magnitude

Central bank need less policy adjustment

# Monetary policy implications when there is 1-unit demand shock and the majority of households have high risk-aversion coefficients

The household readjusts their risk-aversion coefficient and the value tends to converge (again but to different value/distribution)

Output gap still closes very quickly

Inflation converges slower and has higher magnitude

Central bank need more policy adjustment

Tradeoff
